Freshwater Withdrawal by Country and Sector (2013 Update)

Description

As with data table 1, this table on freshwater withdrawals has appeared in some form in every volume of *The World's Water* and remains highly popular. The use of water varies greatly from country to country and from region to region. Data on water use by regions and by different economic sectors are among the most sought after in the water resources area. Ironically, these data are often the least reliable and most inconsistent of all water resources information. This table includes the data available on total freshwater withdrawals by country in cubic kilometers per year and cubic meters per person per year, using national population estimates from 2010. The table also gives the breakdown of that water use by the municipal, agricultural, and industrial sectors, in both percentage of total water use and cubic meters per person per year. Note that "municipal" withdrawals were previously called "domestic" withdrawals and now often include some estimates of commercial and institutional use in the single category.

Data for a number of countries have been updated in this table since the previous volume of *The World's Water*. The AQUASTAT database of the Food and Agriculture Organization of the United Nations (FAO) continues to provide the bulk of the data, but we also work to update water-use data using country-specific sources. The data sources are explicitly identified.

"Withdrawal" typically refers to water taken from a water source for use. It does not refer to water "consumed" in that use. The domestic sector typically includes household and municipal uses as well as commercial and governmental water use. The industrial sector includes water used for power plant cooling and industrial production. The agricultural sector includes water for irrigation and livestock.

Limitations

Extreme care should be used when applying these data. They come from a wide variety of sources and are collected using a wide variety of approaches, with few formal standards. As a result, this table includes data that are actually measured, estimated, modeled using different assumptions, or derived from other data. The data also come from different years, making direct intercomparisons difficult. For example, some water-use data are over twenty years old. Also note that the per capita water-use estimates are computed using withdrawals from different years, but population estimates are normalized for 2010.

As noted in past volumes of *The World's Water*, the FAO AQUASTAT data set, while the most comprehensive single database, contains inadequate information on sources and assumptions and often contains modeled rather than measured values. Data from this database should be used with great care and with appropriate caveats about their quality.

Another major limitation of these data is that they do not include the use of rainfall in agriculture—what is sometimes referred to as "green water." Many countries use a significant fraction of the rain falling on their territory for agricultural production, but this water use is neither accurately measured nor reported in this data set. We repeat our regular call for a systematic reassessment of water-use data and for national and international commitments to collect and standardize this information.
